Assignment 1 Using Informed and Uninformed Search Algorithms to Solve 8-Puzzle

1 Overview

This problem appeared as a project in the edX course ColumbiaX: CSMM.101x Artificial Intelligence (AI). In this assignment, an agent will be implemented to solve the 8-puzzle game.

An instance of the 8-puzzle game consists of a board holding 8 distinct movable tiles, plus an empty space. For any such board, the empty space may be legally swapped with any tile horizontally or vertically adjacent to it. In this assignment, the blank space is going to be represented with the number 0.

Given an initial state of the board, the search problem is to find a sequence of moves that transitions this state to the goal state; that is, the configuration with all tiles arranged in ascending order 0,1,2,3,4,5,6,7,8.

The search space is the set of all possible states reachable from the initial state. The blank space may be swapped with a component in one of the four directions 'Up', 'Down', 'Left', 'Right', one move at a time. The cost of moving from one configuration of the board to another is the same and equal to one. Thus, the total cost of the path is equal to the number of moves made from the initial state to the goal state.

Suppose the program is executed starting from the initial state 1,2,5,3,4,0,6,7,8 as follows:

$$parent = \begin{bmatrix} 1 & 2 & 5 \\ 3 & 4 & \\ 6 & 7 & 8 \end{bmatrix} \implies child = \begin{bmatrix} 1 & 2 \\ 3 & 4 & 5 \\ 6 & 7 & 8 \end{bmatrix}$$

$$parent = \begin{bmatrix} 1 & 2 \\ 3 & 4 & 5 \\ 6 & 7 & 8 \end{bmatrix} \implies child = \begin{bmatrix} 1 & 2 \\ 3 & 4 & 5 \\ 6 & 7 & 8 \end{bmatrix}$$

$$parent = egin{bmatrix} 1 & 2 \\ 3 & 4 & 5 \\ \hline 6 & 7 & 8 \end{bmatrix} \qquad \Longrightarrow \qquad child = egin{bmatrix} 1 & 2 \\ 3 & 4 & 5 \\ \hline 6 & 7 & 8 \end{bmatrix}$$

2 Application

2.1 Algorithms

You will need to implement the 8 puzzle search problem using the four search algorithms:

- BFS
- DFS
- Iterative DFS
- A*

2.2 Heuristics

For the A* (the informed search) we are going to use Manhattan heuristic and Euclidean heuristic and compare the number of nodes expanded and output paths, and report which heuristic is more admissible.

1. Manhattan Distance

It is the sum of absolute values of differences in the goal's x and y coordinates and the current cell's x and y coordinates respectively,

$$h = abs(current_cell:x - goal:x) + abs(current_cell:y - goal:y)$$

2. Euclidean Distance

It is the distance between the current cell and the goal cell using the distance formula

$$h = \operatorname{sqrt}((\operatorname{current_cell:x - goal:x})^2 + (\operatorname{current_cell.y - goal:y})^2)$$

Artificial Intelligence Course Assigned: 16/10/2024 Due: 28/10/2024

3 Notes

You will be given a random initial state and your code should output the goal state 0,1,2,3,4,5,6,7,8. The output should be in a **traceable format**; as every step should be printed. (best visualization of the puzzle table will be grant a bonus).

3.1 Deliverables

- Your well-commented code.
- A report showing your work, including:
 - path to goal
 - cost of path
 - nodes expanded
 - search depth
 - running time

Also the report should contain the data structure used (if any) and the explanation for each algorithm, Assumptions and details you find them necessary to be clarified, Any extra work and Sample runs. You should show your algorithm and how it operates.

3.2 Further Notes

- You may use Java, Python, or C++ for your implementation.
- Copied assignments will be severely penalized.
- You can work in groups of 2 or 3.
